

NationWide

Shipping & logistics platform

1. Context

We are integrating ICL's shipment APIs into the NationWide platform so that customers can look up the live status of their parcels using a NationWide-issued tracking number, which is internally mapped to the corresponding ICL AWB number. We have received and successfully tested the AWB booking API ("Booking API request and response V1") against the UAT environment, and this is working as documented.

To complete the tracking-status side of the integration, we located and tested a second endpoint on the same UAT host that appears to serve exactly this purpose. Before we build against it, we would like ICL to confirm it is the correct, supported endpoint and provide full documentation for it, in the same format as the Booking API document already shared with us.

2. Endpoint We Tested

URL (UAT):

`https://uatcloud.iclinternational.in/api/v1/Tracking/Tracking`

Method: POST

Sample request sent (using the sandbox credentials and AWB number from the Booking API document):

```
{
  "UserId": "TEST1",
  "Password": "test",
  "CustomerCode": "TEST",
  "AWBNo": "6000005372"
}
```

Response received:

```
{
  "Response": {
    "ResponseCode": "RT01",
    "ErrorCode": "0",
    "ErrorDisc": "Success",
    "Tracking": [{
      "AWBNo": "6000005372",
```

```

    "Origin": "HYDERABAD",
    "Destination": "U.S.A.",
    "Status": "",
    "DeliveryDate": "",
    "VendorName": "FEDERAL EXPRESS CORPORATION",
    ... (additional fields)
  }],
  "Events": [],
  "AdditionalData": [],
  "Dimensions": [],
  "Performa": []
}
}

```

Note: Status and Events came back empty for this specific AWB number, which we believe is simply because it is a documentation example that never had a real shipment move through your system — not because those fields are unused. We have not guessed at further AWB numbers, since we do not want to query shipment data that is not ours.

3. What We Are Asking ICL to Confirm/Provide

1. Please confirm whether `/api/v1/Tracking/Tracking (UAT)` / the equivalent production endpoint is the correct, officially supported endpoint for retrieving the current status and movement history of an existing AWB.
2. Full technical documentation for this endpoint, in the same request/response format as the Booking API document already provided — including every field in the request and response, and which fields are mandatory vs. optional.
3. A sample response using a real or realistic AWB number that has actual movement history, so we can see populated values inside the `Tracking.Status` field and the `Events` array (we specifically need the complete list of possible status codes/values and their meanings, along with the structure of each entry in `Events` — e.g. timestamp, location, status, remarks).
4. The exact date/time format and timezone used across all fields (e.g. your own sample has `"InvoiceDate": "02/03/2026"`, which is ambiguous between 2 Feb and 3 Feb depending on format, and `"BookTime": "1912"` with no timezone indicated) — we need this to parse timestamps correctly and avoid silently displaying incorrect times to customers.
5. How the response distinguishes between: (a) an AWB number that does not exist at all, (b) an AWB that exists but has no movement/scan yet, and (c) invalid or expired credentials — i.e. the distinct `ResponseCode/ErrorCode` values for each case, so we

can handle them correctly rather than treating every non-success response the same way.

6. The production base URL and how production API credentials (UserId/Password/CustomerCode) are provisioned and rotated for our account.
7. Whether production access requires our server's IP address(es) to be whitelisted, and if so, the process and typical turnaround time for that.
8. Rate limits or usage quotas for this endpoint (requests per minute/day), and whether they differ between UAT and production.
9. How frequently ICL's own tracking data is refreshed relative to the actual courier scan/event (e.g. near-real-time vs. a batch update once or twice a day) — this determines how often we should poll for updates.
10. Whether a webhook/push-notification mechanism is available for status changes, as an alternative to polling this endpoint.
11. Any published or informal SLA (uptime commitment) and the expected error-response format/behavior on timeout or failure.

4. Why This Matters

This is the last piece required to complete the live tracking integration on the NationWide platform. Everything else — the customer-facing tracking page, the internal-to-ICL tracking number mapping, caching, and the admin dashboard — is already built and tested against a stand-in adapter. Once the above is confirmed, we can wire in the real integration and move to staging validation.

We would appreciate a response at your earliest convenience so we can keep this phase of the project on schedule.
